01 THE OPPORTUNITY

Shoppers Do Come Back.
They Come Back Through Search.

Grow saved-item conversion within 30 days by protecting gross margins, avoiding promotional dilution, and driving organic conversion.

THE MARKET CHECK

51.5M weekly actives — India's largest fashion platform
CLSA, 2026

₹6,043cr FY25 revenue, up 18% year on year
MCA filings

18× profit growth on the **same** demand
MCA filings

~9% of wishlisters buy a saved item within 30 days
= 0.72 × 0.45 × 0.34 × 0.85 (A×B×C×D). Intent measured; B, C, D assumed until day-one instrumentation.

Myntra grows by **converting shoppers it already has**, not by buying new ones.

Demand is already paid for.

THE PREMISE

Four things have to go right for a saved item to sell. Fix any one and the whole number moves — so we picked the ones nobody owns.

A	They meant to buy it — **7 in 10** saves are genuine	near ceiling
B	**Do they come back?** Alerts exist already and cost margin. When they search instead, nothing helps.	unowned
C	**Do they get an answer? 2 in 3** have a doubt we never answer. **1 in 5** who looked gave up.	unowned
D	**Do they buy?** Price stops about **1 in 4** — and price is off-limits	excluded lever

A and D are already handled. B and C are wide open.

THE STRATEGIC GOAL

Take W30 from ~9% to ~11% in eight weeks — on organic conversion, with no discount, coupon or cashback spend behind it.

Why it matters:

For shoppers — the saved item comes back unprompted, and the doubt that stopped them is answered in the same place.

For Myntra — two points is **~200,000** more closed decisions a month, about **₹40 Cr** of incremental GMV.

For margin — every point of that lift is earned without promotional dilution, on demand already paid for.

~9% → ~11% · ≈₹40 Cr/mo · zero discount spend

02 HOW THE DISCOVERY ENGINE WORKS

Live: Discovery Engine ↗

Turning Customer Voice Into Actionable Insight, One Comment at a Time.

Six public sources, five steps — and an audit that changed our own answer.

1. Reading **19,143** comments by hand is slow and inconsistent.
2. One model reads every comment the same way, so nothing is missed or judged differently.
3. Loose complaints become ranked, quotable evidence.

19,143 comments ingested → **3,922** about a buying decision → **12** themes, ranked

WHAT GETS DROPPED, AND WHY

A yes/no check on every comment: **is this about deciding to buy?** Late deliveries, refunds and app bugs go — leaving only pre-purchase doubt.

Collect
19,143 COMMENTS
Six public sources. YouTube alone gave **2,144** of the usable ones. Duplicates removed first.

→

Filter
3,922 KEPT
Keeps only comments about a buying decision. Simple rules, **no AI yet** — fast and free.

→

Group
12 THEMES
Themes emerge from the text, then edited by hand.

→

Label
TAGGED
Each comment carries its theme, severity and journey stage.

→

Rank
SCORED
By how many raise it, how badly it blocks, how fixable it is.

✓ HOW FAR WE TRUST IT

We audited **50 documents by hand** and found two real mistakes — one fixed, one written down and still open. Nearly **9 in 10** labelled comments carry a quote we can point to, and re-labelling lands in the same theme about **two-thirds** of the time. The order is solid; the exact percentages are not.

⚠ WHAT IT CAN'T TELL US

Fewer than 2 in 100 comments mention a wishlist at all. People write reviews about products. This data can rank doubts — it says nothing about coming back to a saved item.

The **3,922** usable comments: YouTube **2,144**, competitor apps **905**, Play **409**, Reddit **338**, App Store **126**

Brand-scoped searches returned useful results **3× as often** as broad ones — a corpus only tells you about the words you went looking for

03 WHAT THE ENGINE FOUND

The Data Speaks: Trust and Fit Win.
Our Feature Ranks Ninth and Twelfth.

What 19,143 comments settled, what they could not — and the four claims left for primary research to test.

RANKED BLOCKERS · SHARE WHO RAISE IT

Across 3,017 Myntra comments about a buying decision.

Quality & seller trust	23%
Unreliable size & fit	20%
Difficult returns	10%
Missing product details	9%
Misleading photos	8%
The wishlist itself two themes, 9th and 12th	1%

Returns hurt badly when they happen — but **hurting is not the same as stopping the sale**.

ONE BARRIER, NOT FOUR

The doubts people actually name:

Will it fit me?	46%
Is the fabric right?	17%
Can I trust the seller?	15%
Will the colour match?	13%

One failure, not four: 9 in 10 doubts are things the page cannot verify.

Two in three hit a barrier they cannot resolve.

WHAT THE ENGINE CANNOT SETTLE

Does it stop the sale, or only delay it?

What brings someone back to a saved item?

Would answering it change the decision?

Fewer than 2 in 100 comments mention a wishlist — reviews are written after delivery. Primary research had to settle these, as four claims with tests.

CLAIM 1

Fit uncertainty is the single largest blocker.

Size & fit · 46% of named doubts

THE TEST

Disproved if shoppers rank price above fit when asked.

CLAIM 2

The doubt cannot be resolved on the product page.

Blocked before buying: 2 in 3

THE TEST

Disproved if the answer was on the page and they missed it.

CLAIM 3

Returns are a post-purchase grievance, not a blocker.

Ranked 3rd on raw counts only

THE TEST

Disproved if returns still rank once the split is applied.

CLAIM 4

The wishlist itself is not what people complain about.

Two wishlist themes, both near the bottom of twelve

THE TEST

Disproved if wishlist usability is named in research.

04 TALKING TO SHOPPERS

Live: User Research ↗

Where Data Meets Human Truth:
Naming the Moment of Doubt.

Primary research: 16 survey responses and 11 prototype testers across two rounds — a method that never asks anyone to hand over a real wishlist.

✓ WHAT IT CONFIRMED

- ✓ Fit-type worries are real and widespread — fabric, photos, "will it suit me", sizing: **more than half** the lists we looked at.
- ✓ The doubt really does go unanswered. Of those who went looking for an answer, **1 in 5 came back empty-handed**.

✗ WHAT IT CHANGED

- ✗ Asked for their single biggest blocker, **half said price or a sale** — not fit.
- ✗ A reason the data never surfaced: *"I'd forgotten about it until now."*
- ✗ **More than a third** get stuck comparing. And **four of eleven** prototype testers named a blocker our data has no word for — *can't tell them apart, might be out of style, don't know what it goes with.* Not a missing fact. An unfinished decision.

01 · SAVE

The shopper saves something because it might matter later.

02 · SEARCH AGAIN

Days later they search again, carrying none of that context.

03 · RECONNECT

The step nothing does today — the saved item should reappear.

04 · RESUME

The decision resumes instead of restarting.

WHY BOTH ANSWERS ARE RIGHT

Fewer than 2 in 100 comments mention a wishlist — reviews are written after delivery, so nobody writes about it. Silence is not evidence it works.

Ask about a saved item right now and the blocker isn't missing information — it is a decision left open and never picked back up.

16 survey responses | **11** testers on the live prototype | **27** responses across two studies

05 THE PROBLEM, STATED

The Wishlist Remembers What You Saved.
It Forgets Why You Cared.

The wishlist answers none of the four doubts that stop a saved purchase. Segment: fit-uncertain & low-trust shoppers (48%).

⚖ THE PROBLEM, IN NUMBERS

W30 near 9% — nine in ten saved items go unbought inside 30 days.
2 in 3 name a doubt we never answer; **1 in 5** who looked came back empty.
Every lever there is monetary — **each leaves the item sitting**.

FIVE WHYS — METRIC TO ROOT CAUSE

1	Saved items don't get bought	objective
2	*"not sure it'll fit" · "can't tell them apart" · "I'll come back to it"*	measured
3	**The wishlist saves the item, not the question**	measured
4	What would settle it never reaches this shopper	survey
5	**So the shopper carries the risk of being wrong**	to test

THE VALUE TO THE SHOPPER

They screenshot into WhatsApp, hunt reviews, keep the real shortlist in Notes — and **order two sizes to return one, money up front**. We handed them the cost of their own doubt.

WHAT THE RESEARCH PRODUCED

19,143 comments discovery engine

Twelve blockers ranked: trust **23%**, fit **20%**. The wishlist itself ranks **9th and 12th** — fewer than 2 in 100 comments mention one at all.

16 survey responses primary research

Half name price or a sale, **more than a third get stuck comparing**, and one reason the corpus never surfaced: *"I'd forgotten about it until now."*

11 prototype testers two rounds, live build

All eleven found the saved item; **five still could not say why it appeared**. Four named a blocker the corpus has no word for.

HOW THE THINKING MOVED, STAGE BY STAGE

Business metric → four terms; two unowned
Product outcomes → they re-enter alone, the doubt gets answered
AI discovery → 19,143 comments, blind to re-entry
Primary research → doubt confirmed, moment moved
Problem definition → item kept, question discarded

✪ THE TAKEAWAY

Not buying isn't indecision. When the shopper carries all the risk, waiting is the sensible move.
If the prototype study shows people simply didn't know rather than didn't want to be wrong, step 5 is wrong — we keep step 3, drop the risk framing, and say so. ↗

06 PRIORITISATION

We Ranked Eighteen Ways to Fix the Wishlist.
Then the Evidence Moved Us Off the Wishlist.

Scored on evidence, moat, build and demo rather than RICE — reach is identical across all three, so it separates nothing.

DIRECTION 1 PARTLY TAKEN

Make the wishlist itself decidable. Ask why it was saved, sort the list into decision states, answer fit and worth-it on one card, duel the near-duplicates.

WHY IT LOSES — every part of it waits for the shopper to open the wishlist. A better list that nobody opens changes nothing.

DIRECTION 2 NOT THE HEADLINE

Answer fit directly. Match the shopper to people with the same keep-and-return history: *"your fit twins bought this in L — 9 of 11 kept it."*

WHY IT LOSES — the best use of data only Myntra holds, but it answers one doubt and leaves comparison, staleness and pairing untouched.

DIRECTION 3 BUILT

Reconnect at the search moment. The saved item comes back while they are typing, carrying the evidence that settles it.

WHY IT WINS — the only direction that fires without the shopper remembering to come back, and the only one that answers the doubt in the same moment.

SCORED ACROSS EIGHTEEN IDEAS, BEFORE WE KNEW WHICH WOULD WIN	EVIDENCE	MOAT	BUILD	DEMO	DECISION
Verdict Card — fit, wardrobe, evidence, worth-it	5	5	4	5	**Fused in** — it is the confidence panel
The Duel — collapse the near-duplicates	5	2	5	5	**Fused in** — it is the compare screen
Fit Twins — a cohort with the same return history	5	5	4	4	Rejected as the headline

15 of the 18 never made the deck | the three shown **scored highest** | the winner changed **after** the research, not before

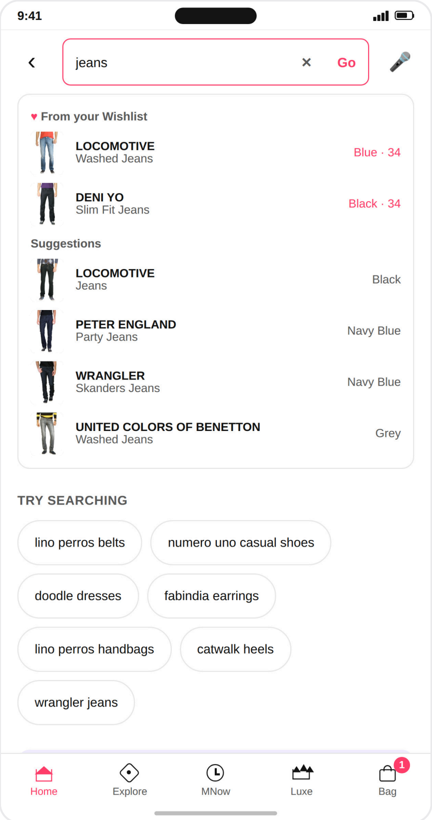
07 WHAT WE BUILT

Live: Prototype ↗

Reuniting Shoppers With What They Love Before They Even Ask.

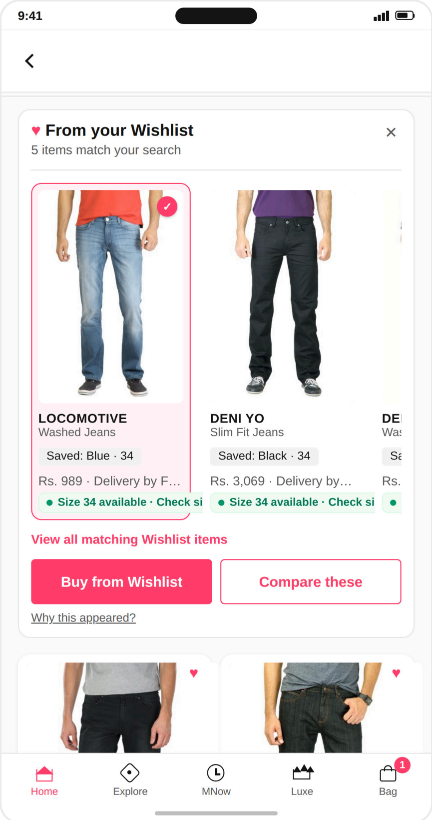
The search-interruption prototype: five screens, one decision. All captured from the working build.

1 · INTERRUPTION



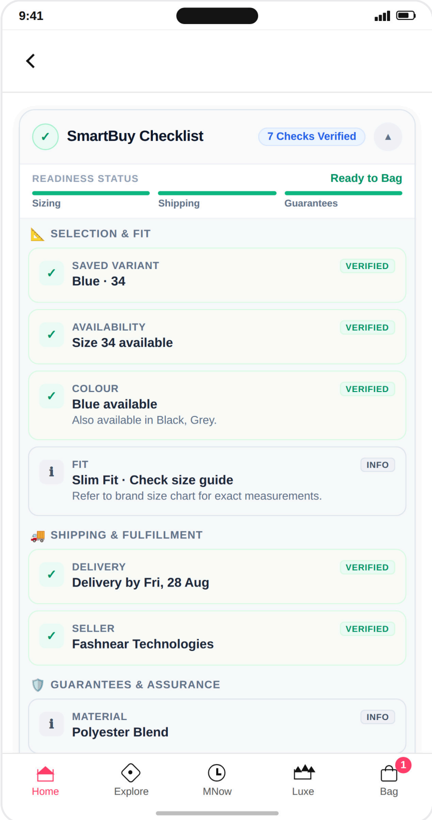
The one that matters most. They return before you search.

2 · RECONNECTION



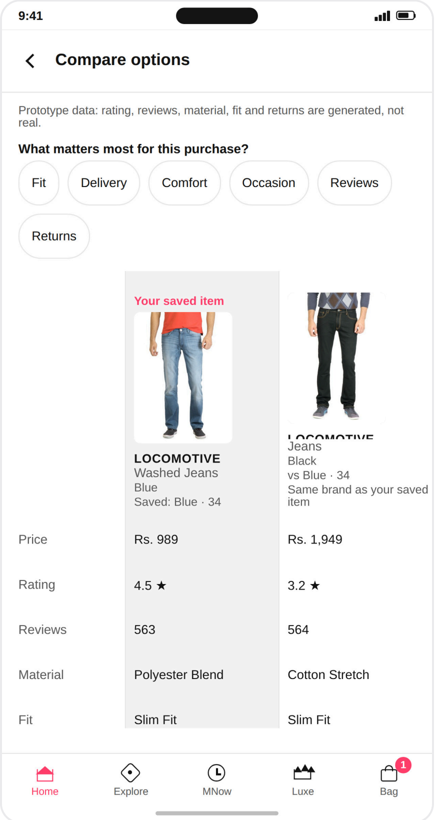
Three items at most, two equal paths, ranking unchanged.

3 · CONFIDENCE



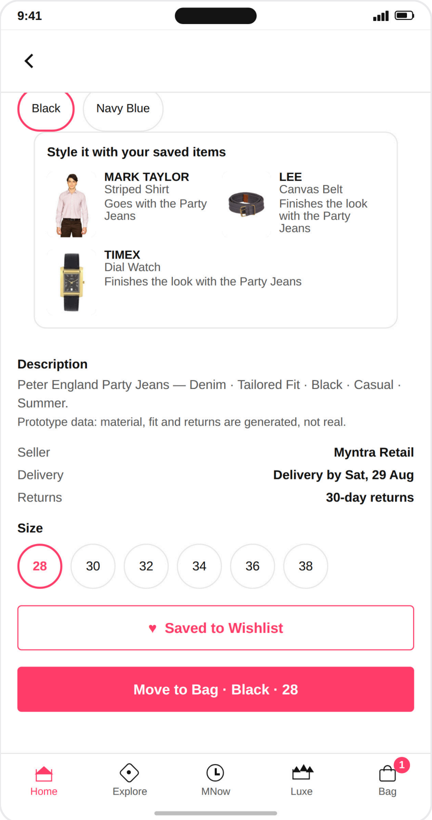
Ten checks, each naming its source. **Fit says "info", never a score.**

4 · COMPARISON



Sorting by what matters reorders rows. It hides none.

5 · STYLING



"I don't know what it goes with." Four at most, all saved.

WHY THE FIRST SCREEN CARRIES THE PRODUCT

Every screen after it assumes the shopper remembers saving the item. **Typing is the only moment where that's still an open question** — and it costs nothing.

Saved items sit in a labelled group *above* the suggestions, colour and size spelled out. **Not certain it's a match? The group doesn't appear.**

THE RULES WE HELD OURSELVES TO

No discounts or urgency. No notifications. Search never waits for us. When in doubt, show nothing. Accessibility blocks launch.

And what we chose not to build: a fit score, a review verdict, a seller-trust rating, stock levels, image search. **The data can't support them, and we say so.**

THE TAKEAWAY

The interruption is the product. Everything after it is the shopper finishing a decision they'd already started.

546 automated tests, all ten acceptance checks passing, no wrong-variant substitutions in a 10,000-run stress test, and no measurable cost to search speed.

08 WHAT TESTERS SAID

Live: Prototype Survey ↗

A Promising First Step:
Users Found It, Trust Is Still a Work in Progress.

Eleven people across two rounds, five minutes each. Counts, not percentages — a direction, not a result.

✓ WHAT HELD UP

- ✓ **All eleven** found a wishlisted item while searching — ten spotted it right away.
- ✓ **Nine of eleven** would actually wear the pairing the module suggested — one never found it.
- ✓ **All nine who compared** said reordering helped them decide.

✗ WHAT DIDN'T

- ✗ **Five of eleven** still could not say clearly why the item appeared. Deciding in place got *worse* between rounds — **3 of 5, then 1 of 6**.
- ✗ One found a real defect: **an item removed from the wishlist still came back, still labelled saved**.
- ✗ "It answered my doubt": **3.4** then **4.0** — improving, still mid-scale.

WHAT THEY ASKED FOR, IN THEIR OWN WORDS

"It said 'good match' but didn't say why, or whether it'd actually fit someone my height."
Relevance, not evidence — not why it fits *you*.

"Let me save my 'winner' after comparing so I don't have to redo it next time."
The judgement is reached, then discarded.

"I'd want to know if a new collection has come in that's better looking than the one I saved."
Staleness — absent from 19,143 comments.

ELEVEN TESTERS, TWO ROUNDS — THE COUNTS

11/11	6/11	4/11	5/11
found the saved item	could say why	decided in place	want a price alert

WHAT'S STOPPING THEM — ALL 11 BLOCKERS

Price — the excluded lever	4
Doubts we have no word for	4
Fit, quality, or nothing	3

THE TAKEAWAY

Eleven found it. Six could say why. The mechanic works — the explanation does not, yet.
Same question both rounds: **none of the first five named a price alert, then five of six did**. At n=11 that answer is unstable, and the live A/B settles it — not the panel. ↗

09 HOW WE'LL KNOW IT WORKED

One Number We Mean to Move.
Four That Must Not Move With It.

8-week user-level A/B — Control: search vs Treatment: reconnection module — ~7,200 users/arm (95/80% power, +15% MDE).

★ NORTH STAR METRIC

W30 — wishlist-to-purchase conversion = wishlisters who buy at least one saved item within 30 days ÷ all wishlisters.

Bought = counted **after returns** — the honest number. · **Wishlist-to-bag** (item-level, ~15% benchmark) is a **diagnostic**, not the north star.

▶ LEADING INDICATORS

They move first. If these stay flat, the north star never will.

Module reach and use — does the saved item appear in the search, and is it tapped? Without this, a flat result is unreadable.

Decisions closed — bought *or* deliberately removed ÷ all saved items. Counts deciding, not just selling.

Time a decision stays open — days from save to a resolution either way. Three days beats thirty.

⚠ GUARDRAIL METRICS

These must not break, even if the north star rises.

Return rate on helped items — a wrong-size push destroys the value behind the win.

Dismissal rate — catches a module people quietly learn to ignore.

Basket size — catches the cheap win of steering shoppers to cheaper things.

Search latency — core search must not slow; the module fails open at 30ms.

◉ TARGETS — FIRST EIGHT WEEKS

North star — W30, **+15% relative**

today ~9%

8 weeks ~11%

Leading indicators

Tapped by **2 in 5** · decisions closed **1 in 3** → **4 in 10** · time falling.

Guardrails

Returns **no higher than normal** · dismissals, basket, speed unchanged.

*9% is modelled, not measured; external wishlist-to-purchase benchmarks run **5–20%**.*

THE TAKEAWAY

Passing our own tests proves the feature works as built. It proves nothing about whether shoppers buy more.

One result we've committed to in advance: **deliberate removals will go up, and that is success** — closing a decision the other way still closes it. If purchases rise but returns rise with them, we don't ship.

10 RISKS, ROLLOUT AND WHAT'S NEXT

Charting the Path Forward: Embracing Risk, Demanding Clarity.

Four ways this fails, the response agreed in advance for each, and the three phases that would prove it.

⚠ FAILURE MODES & MITIGATION

The test group is too small biggest risk

Risk — 300–500 testers; the lift needs **~19,000** to detect, **~120,000** to explain. **Mitigation** — they test comprehension; the read runs live.

One wrong match and the module is dead

Risk — a false "you saved this" is unrecoverable; the next correct one isn't believed. **Mitigation** — exact matching only, nothing shown below the bar.

The module slows core search

Risk — latency added to search costs more than this feature earns. **Mitigation** — IndexedDB match **<0.1ms**, **30ms fail-open**.

A shared device exposes someone's saved items

Risk — reconnection on a logged-out or shared session leaks a private list. **Mitigation** — signed-in only; signed out, the module shows nothing. Tested, and a launch blocker.

▶ ROLLOUT — THREE PHASES

Phase 1 · Comprehension weeks 1–2

300–500 testers on the live prototype. **Goal** — does it read as "you saved this", does dismissal work, is the removed-item defect gone. Plus a **shadow pass**: matches logged, nothing shown.

Phase 2 · Live A/B weeks 3–10

User-level split, **~7,200 per arm**, search against the module. **Goal** — W30 **9%** → **11%**, returns flat.

Phase 3 · Ramp or kill week 11+

Ramp only if returns hold. Seen at volume and nothing moves — **a kill, not an iteration**.

WHAT WINNING LOOKS LIKE AT EIGHT WEEKS

Shoppers — the item returns unprompted, doubt answered.

Myntra — **≈₹40 Cr/mo** GMV, decisions **1 in 3** → **4 in 10**.

Instrument first — W30 measured, not modelled. **Fix the removed-item defect** — launch blocker. **Set the kill date** — week 11, in advance.

THE TAKEAWAY

One rule we broke on purpose: our own notes said this data couldn't justify a wishlist feature. We built one anyway — and wrote down why, with the date.

Honest limits: today's 9% is modelled rather than measured, and these tests guard against regressions rather than prove shoppers buy more.
